
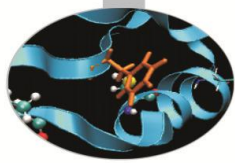
HPC Architectures – past ,present and emerging trends

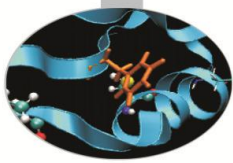
Andrew Emerson, Cineca
a.emerson@cineca.it

Agenda



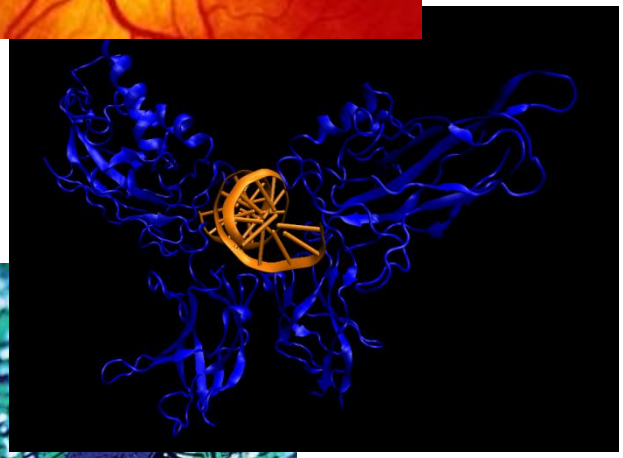
- Computational Science
- Trends in HPC technology
- Trends in HPC programming
  - Massive parallelism
  - Accelerators
  - The scaling problem
- Future trends
  - Memory and accelerator advances
  - Monitoring energy efficiency
- Wrap-up

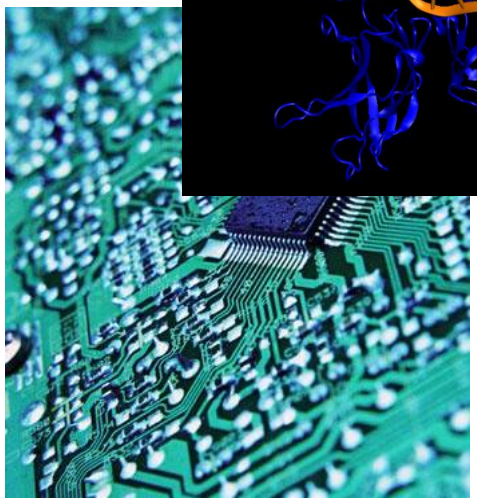
Computational Science

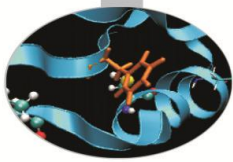


"Computational science is concerned with constructing mathematical models and quantitative analysis techniques and using computers to analyze and solve scientific problems. In practical use, it is typically the application of computer simulation and other forms of computation from numerical analysis and theoretical computer science to *problems in various scientific disciplines."* (Wikipedia)

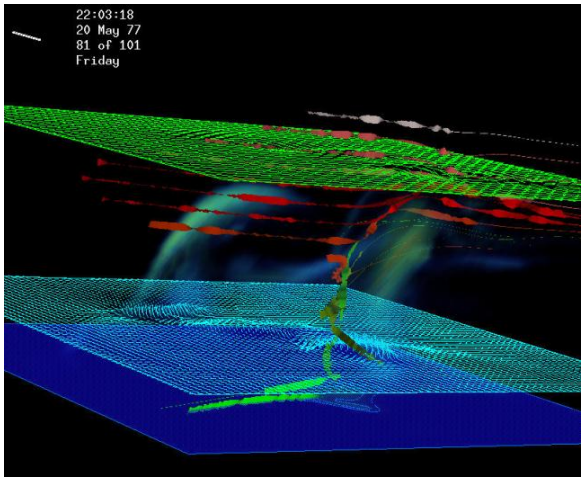
Computational science (with theory and experimentation), *is the "third pillar" of scientific inquiry,* enabling researchers to build and test models of complex phenomena.



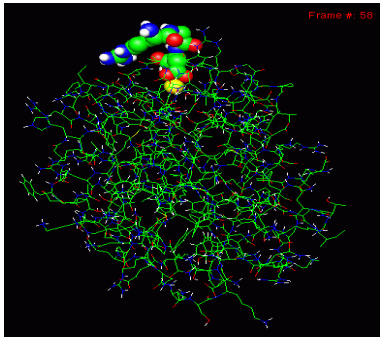




Computational Sciences



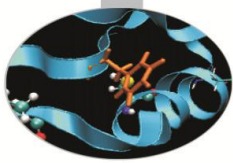
Computational methods allow us to study complex phenomena, giving a powerful impetus to scientific research.



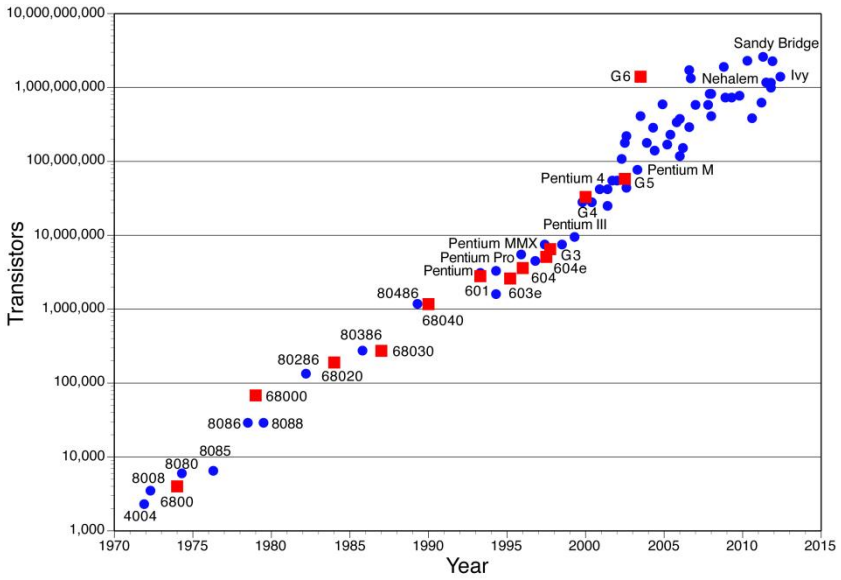
The use of computers to study physical systems allows to manage phenomena

- **very large**
  (meteo-climatology, cosmology, data mining, oil reservoir)
- **very small**
  (drug design, silicon chip design, structural biology)
- **very complex**
  *(f*fundamental physics*, fluid dynamics, turbolence)*
- **too dangerous or expensive**
  *(fault simulation, **nuclear** tests, crash analysis)*

Which factors limit computer power?

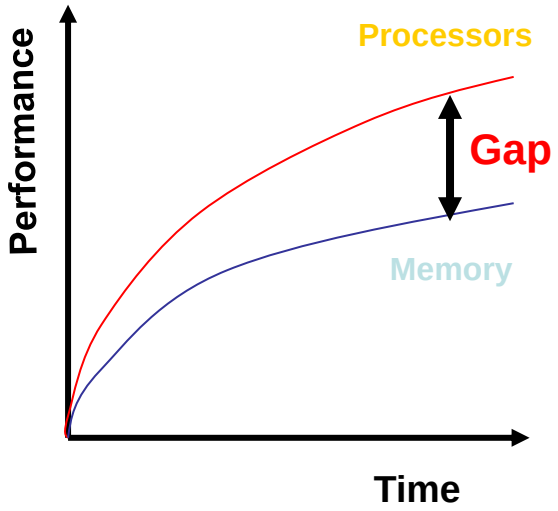


we can try and increase the speed of microprocessors but ..

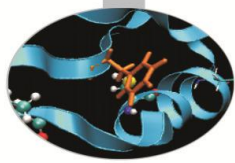


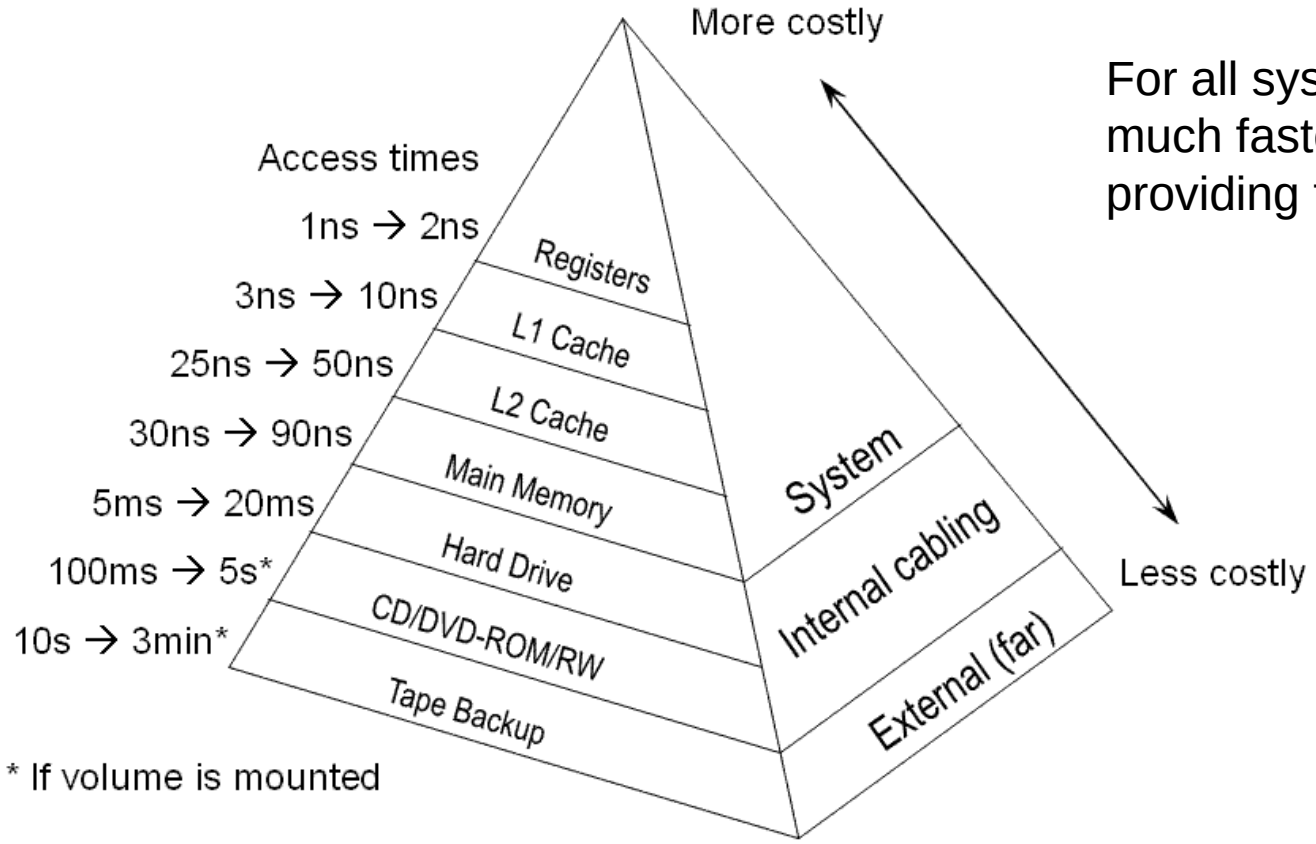
.. the bottleneck between CPU and memory and other devices is growing

Moore's law gives only a slow increase in CPU speed. (It is estimated that Moore's Law will still hold in the near future but applied to the number of cores per processor) and ..



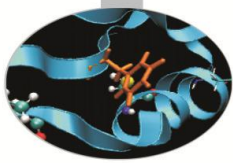
Memory Hierarchy





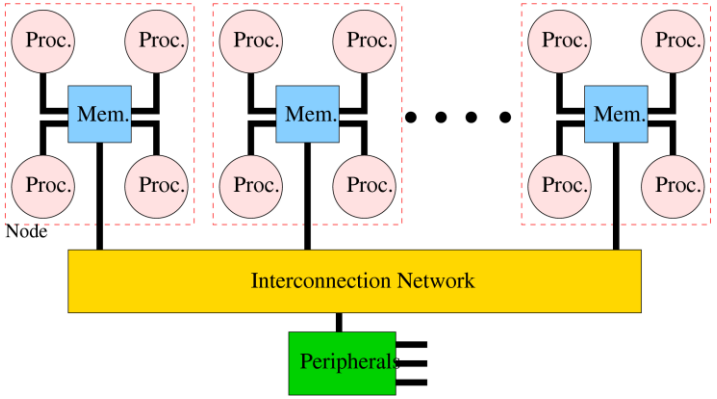
For all systems, CPUs are much faster than the devices providing the data.

HPC Architectures



The main factor driving performance is *parallelism*. *This can be on many levels:*

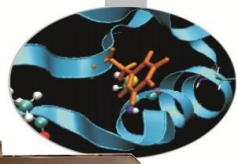
- *Instruction level parallelism*
- *Vector processing*
- *Cores per processor*
- *Processors per node*
- *Processors + accelerators (for hybrid)*
- *Nodes in a system*



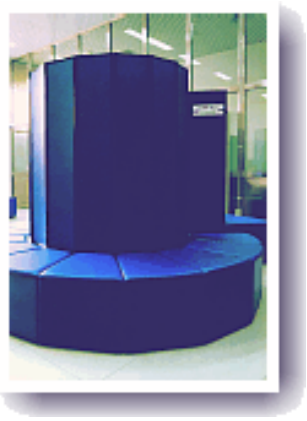
Performance can also derive from device technology

- *Logic switching speed and device density*
- *Memory capacity and access time*
- *Communications bandwidth and latency*

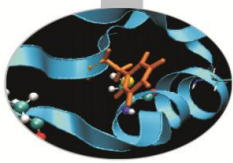
HPC systems evolution in CINECA



1969: CDC 6600 1st system for scientific computing
1975: CDC 7600 1st supercomputer
1985: Cray X-MP / 4 8 1st vector supercomputer
1989: Cray Y-MP / 4 64
1993: Cray C-90 / 2 128
1994: Cray T3D 64 1st parallel supercomputer
1995: Cray T3D 128
1998: Cray T3E 256 1st MPP supercomputer
2002: IBM SP4 512 1 Teraflops
2005: IBM SP5 512
2006: IBM BCX 10 Teraflops
2009: IBM SP6 100 Teraflops
2012: IBM BG/Q 2 Petaflops
2016: Lennovo (Marconi) 13 Pflops



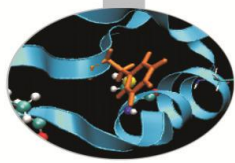
HPC architectures/1



The are several factors that have an impact on the system architectures incl:

1. Power consumption has become a primary headache.
2. Processor speed is never enough.
3. Network complexity/latency is a main hindrance.
4. Access to memory.

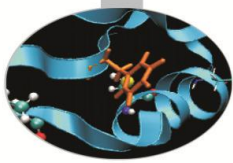
HPC architectures/2



Two approaches to increasing supercomputer power, but at the same time limiting power consumption:

1. Massive parallelism (IBM Bluegene range).
2. Hybrids using accelerators (GPUs and Xeon PHIs).

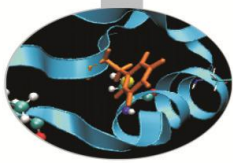
IBM BG/Q



- BlueGene systems link together tens of thousands of low power cores with a fast network.
- In some respects the IBM BlueGene range represents one extreme of parallel computing

Name: Fermi (Cineca)
Architecture: IBM BlueGene/Q
Model: 10 racks
Processor Type: IBM PowerA2, 1.6 GHz
Computing Cores: 163840
Computing Nodes: 10240, 16 core each
RAM: 16 GB/node, 1GB/core
Internal Network: custom with 11 links -> 5D Torus
Disk Space: 2.6 PB of scratch space
Peak Performance: 2PFlop/s

Hybrid systems



- Second approach is to *"accelerate" normal processors* by adding more specialised devices to perform some of the calculations.
- The approach is not new (maths co-procs, FPGAs, video-cards etc) but became important in HPC when Nvidia launched CUDA and GPGPUs.
- Capable of more Flops/Watt compared to traditional CPUs but still relies on parallelism (many threads in the chip).

Model: IBM PLX (iDataPlex DX360M3)
Architecture: Linux Infiniband Cluster
Nodes: 274
Processors: 2 six-cores Intel Westmere 2.40 GHz per node
Cores: 12 cores/node, 3288 cores in total
GPU: 2 NVIDIA Tesla M2070 per node (548 in total)
RAM: 48 GB/node, 4GB/core
Internal Network: Infiniband with 4x QDR switches
Disk Space: 300 TB of local scratch
Peak Performance: 300 TFlop/s

Hybrid Systems/2

- In the last few years Intel has introduced the Xeon PHI accelerator based on MIC (Many Integrated Core) technology.
- Aimed as an alternative to NVIDIA GPUs in HPC.

Model: Eurora prototype
Architecture: Linux Infiniband Cluster
Processor Type:
- ❑Intel Xeon (Eight-Core SandyBridge) E5-2658 2.10 GHz
- ❑Intel Xeon (Eight-Core SandyBridge) E5-2687W 3.10 GHz

Number of cores: 1024 (compute)
Number of accelerators: 64 nVIDIA Tesla K20 (Kepler) + 64 **Intel Xeon Phi (MIC)**
OS: RedHat CentOS release 6.3, 64 bit

THE GREEN 500

The **Eurora supercomputer was ranked 1st in the June 2013 Green500 chart**.

Galileo

Model: IBM NeXtScale
Architecture: Linux Infiniband Cluster
Nodes: 516
Processors: 2 8-cores Intel Haswell 2.40 GHz per node
Cores: 16 cores/node, 8256 cores in total
Accelerator: 2 Intel Phi 7120p per node on 384 nodes (768 in total)
RAM: 128 GB/node, 8 GB/core
Internal Network: Infiniband with 4x QDR switches
Disk Space: 2.5 Pb (Total)
Peak Performance: 1 PFlop

Hybrid Systems/3 - Marconi

- New Flagship system of Cineca replaces Fermi (BG/Q).
- 3 phase introduction: phase A1 already in production, A2 has arrived and is being installed.

A1: a preliminary system going into production in July 2016, based on Intel® Xeon® processor E5-2600 v4 product family (Broadwell) with a computational power of **2Pflop/s**.
A2: by the end of 2016 a new section will be added, equipped with the next-generation of the Intel Xeon Phi product family (Knights Landing), based on a many-core architecture, enabling an overall configuration of about 250 thousand cores with expected additional computational power of approximately **11Pflop/s**.
A3: finally, in July 2017, this system is planned to reach a total computational power of about **20Pflop/s** utilizing future generation Intel Xeon processors (Skylake)

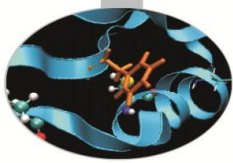
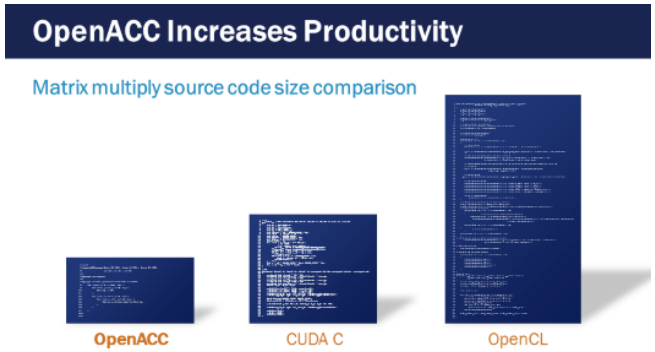
Parallel Software Models



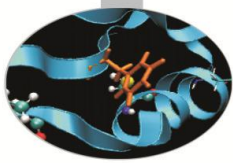
- How do we program for supercomputers?
- C/C++ or FORTRAN, together with one or more of
  - Message Passing Interface (MPI)
  - OpenMP, pthreads, hybrid MPI/OpenMP
  - CUDA, OpenCL, OpenACC, compiler directives
- Higher Level languages and libraries
  - Co-array FORTRAN, Unified Parallel C (UPC), Global Arrays
  - Domain specific languages and data models
  - Python or other scripting languages

python™



OpenCL

Message Passing: MPI



Main Characteristics

- Implemented as libraries
- Coarse grain
- Inter-node parallelization (few real alternatives)
- Domain partition
- Distributed Memory
- Long history and almost all HPC parallel applications use it.

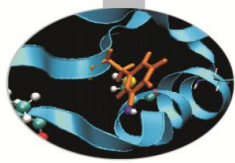
Open Issues

- Latency
- OS jitter
- Scalability
- High memory overheads (due to program replication and buffers)

Debatable whether MPI can handle millions of tasks, particularly in collective calls.

```
call MPI_Init(ierror)
call MPI_Comm_size(MPI_Comm_World,
size, ierror)
call MPI_Comm_rank(MPI_Comm_World,
rank,ierror)
call MPI_Finalize(ierror)
```

Shared Memory: OpenMP

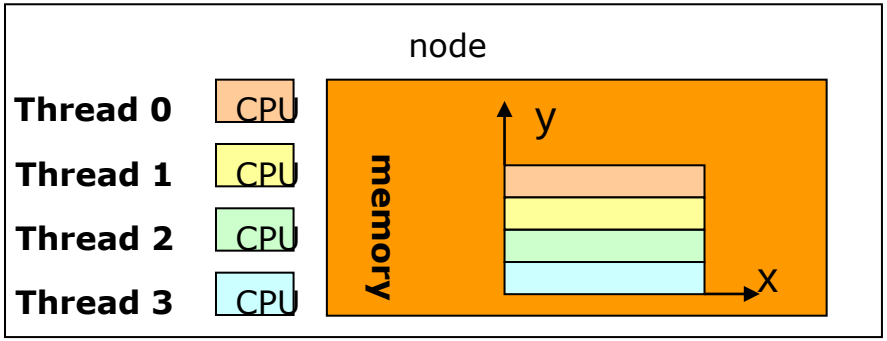


Main Characteristics

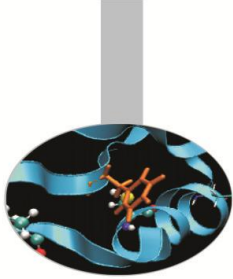
- Compiler directives
- Medium grain
- Intra-node parallelization (p-threads)
- Loop or iteration partition
- Shared memory
- For Many HPC Applications easier to program than MPI (allows incremental parallelisation)

Open Issues

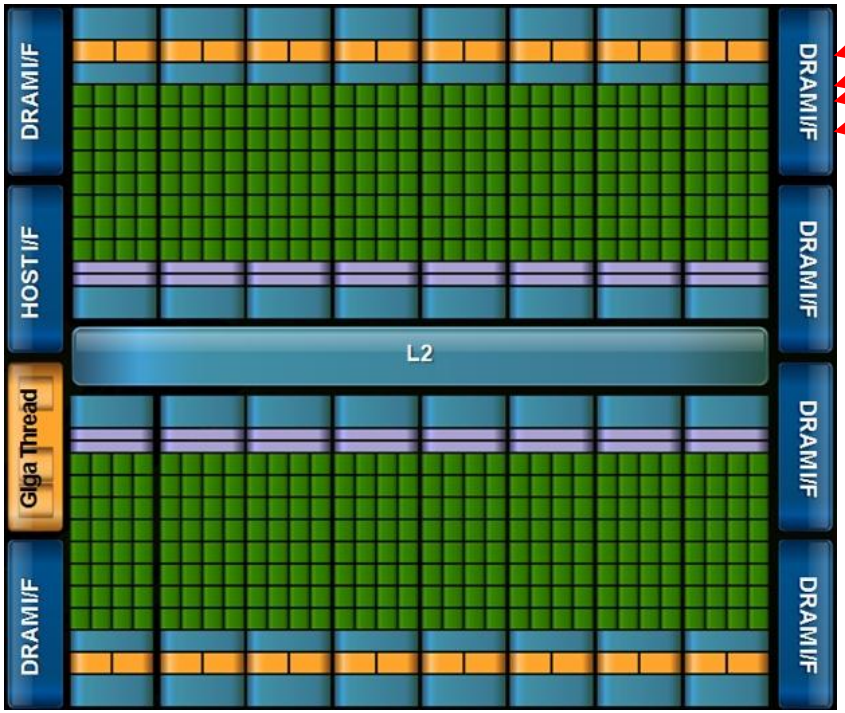
- Thread creation overhead (often worse performance than equivalent MPI program)
- Memory/core affinity
- Interface with MPI

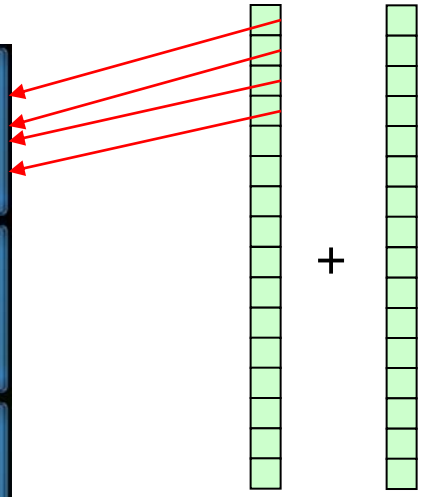


Threads communicate via variables in shared memory



Accelerator/GPGPU

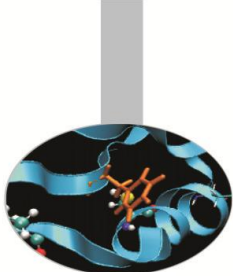




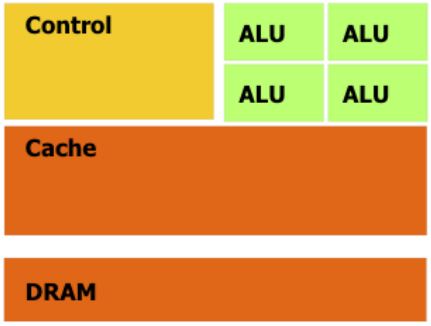
Sum of 1D array

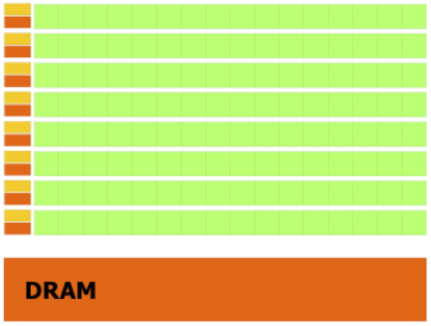
```
__global__ void  GPUCode( int* input1,
int*input2, int* output, int length)
{
  int idx = blockDim.x * blockIdx.x +
threadIdx.x;
  if ( idx < length ) {
     output[ idx ] = input1[ idx ] +
input2[ idx ];
                }
}
```

Exploit massive stream processing capabilities of GPGPUs which may have thousands of cores



NVIDIA/CUDA





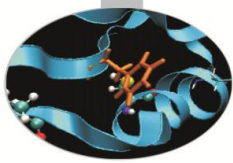
Main Characteristics

- Ad-hoc compiler
- Fine grain
- offload parallelization (GPU)
- Single iteration parallelization
- Ad-hoc memory
- Few HPC Applications

Open Issues

- Memory copy (via slow PCIe link)
- Standards
- Tools, debugging
- Integration with other languages

Accelerator/Xeon PHI (MIC)



The Xeon PHI co-*processor based on Intel's* Many Integrated Core (MIC) Architecture combines many cores (>50) in a single chip.

Main Characteristics

- Standard Intel compilers and MKL library functions.
- Uses C/C++ or FORTRAN code.
- Wide (512 bit) vectors
- Offload parallelization like GPU but *also "native" or symmetric modes.*
- Currently very few HPC Applications

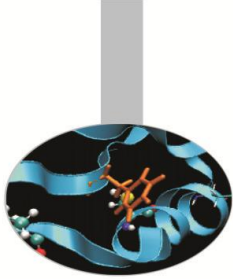
Open Issues

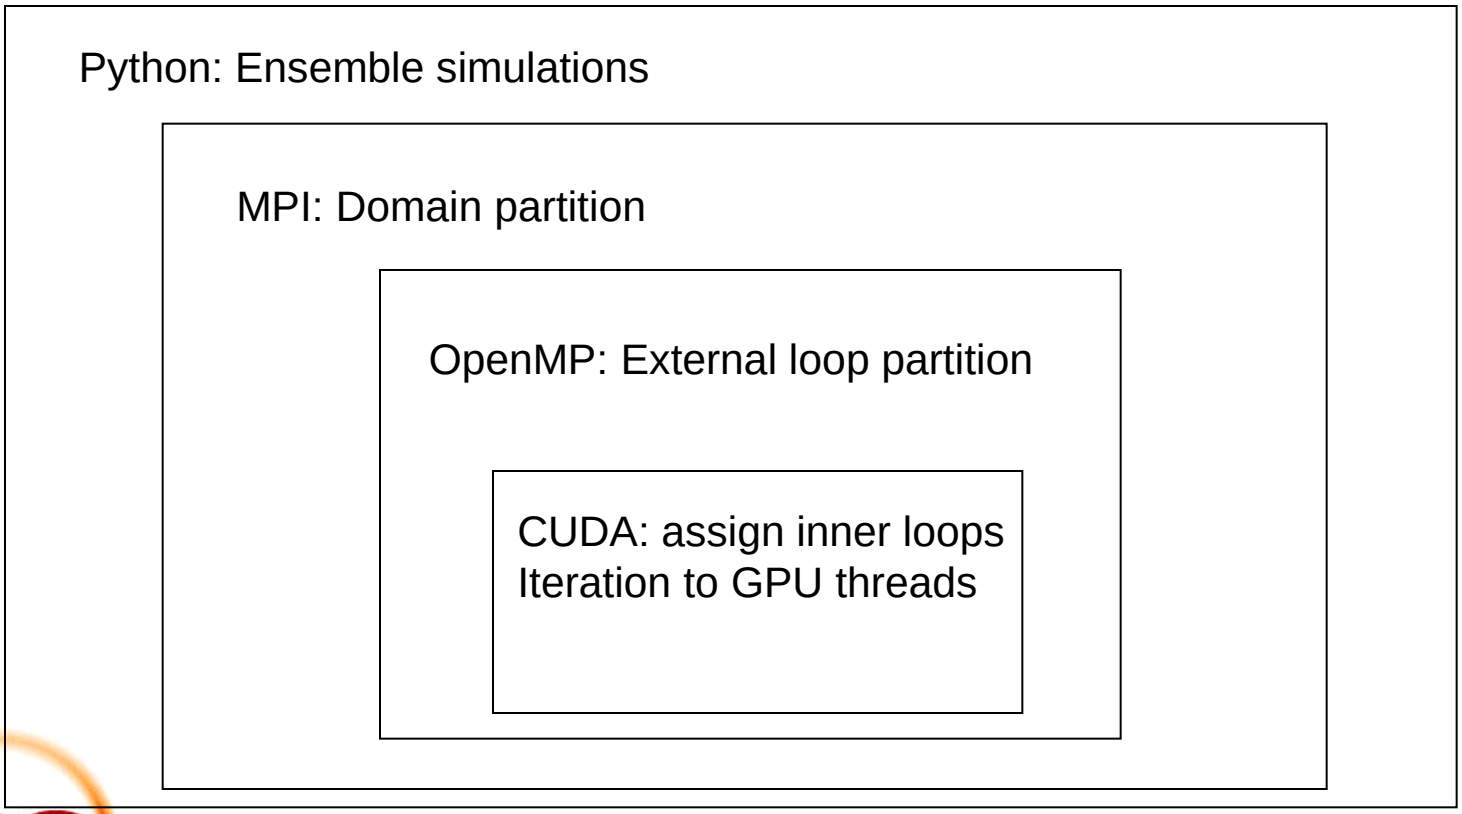
For Knight's Corner:

- Memory copy via slow PCIe link (just like GPUs).
- Internal (ring) topology slow.
- Wide vector units need to be exploited, so code modifications probable.
- Best also with many threads

```
ifort -mmic -o exe_mic prog.f90
```

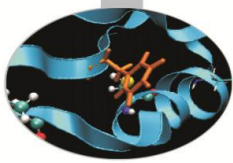
Putting it all together -Hybrid parallel programming (example)





Quantum ESPRESSO http://www.qe-forge.org/

Software Crisis



Real HPC Crisis is with Software

A supercomputer application and software are usually much more long-lived than a hardware

- Hardware life typically four-five years at most.
- Fortran and C are still the main programming models

Programming is stuck

- *Arguably hasn't changed so much since the 70's*

Software is a major cost component of modern technologies.

- The tradition in HPC system procurement is to assume that the software is free.

It's time for a change

- Complexity is rising dramatically
- Challenges for the applications on Petaflop systems
- Improvement of existing codes will become complex and partly impossible.
- The use of O(100K) cores implies dramatic optimization effort.
- New paradigm as the support of a hundred threads in one node implies new parallelization strategies
- Implementation of new parallel programming methods in existing large applications can be painful

Hardware and Software advances comparison

PERFORMANCE

1970

```
      PROGRAM HELLO
C
       REAL A(10,10)
       DO 50 I=1,10
          PRINT *,'Hello'
50     CONTINUE

       CALL DGEMM(N,10,I,J,A)
```

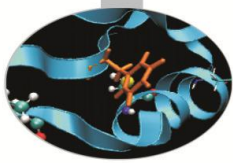
2015

```
      PROGRAM HELLO
C
       REAL A(10,10)
       DO 50 I=1,10
          PRINT *,'Hello'
50     CONTINUE

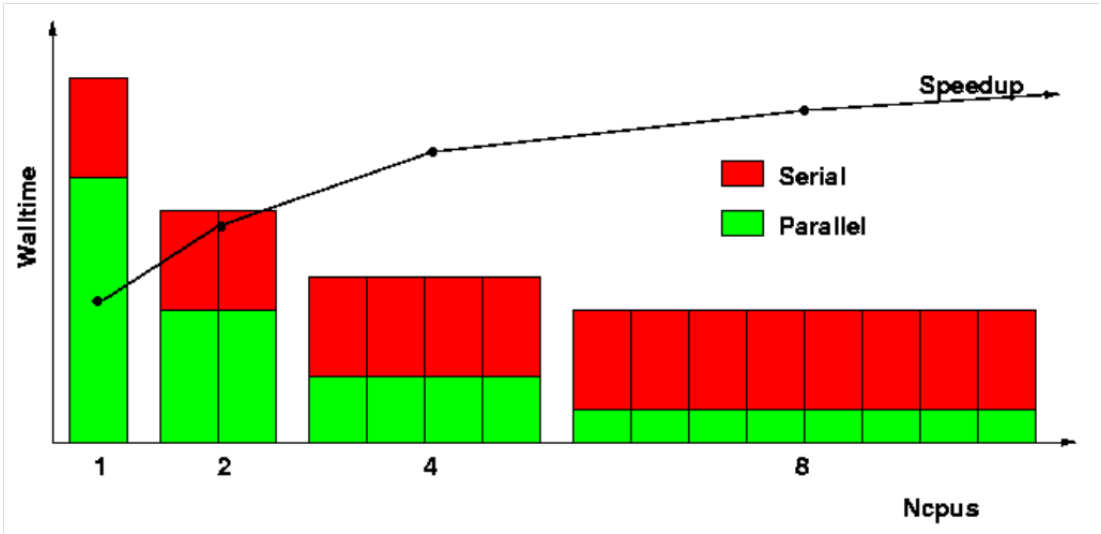
       CALL DGEMM(N,10,I,J,A)
```

SOFTWARE

The problem with parallelism…



In a massively parallel context, an upper limit for the scalability of parallel applications is determined by the fraction of the overall execution time spent in non-scalable operations (Amdahl's law).



For N=no. of procs and P=parallel fraction
max. speedup S(N) is given by

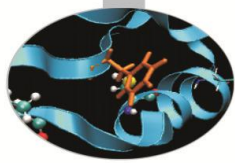
$$S(N) = \frac{1}{(1-P) + \frac{P}{N}}$$

$$N \rightarrow \infty,$$

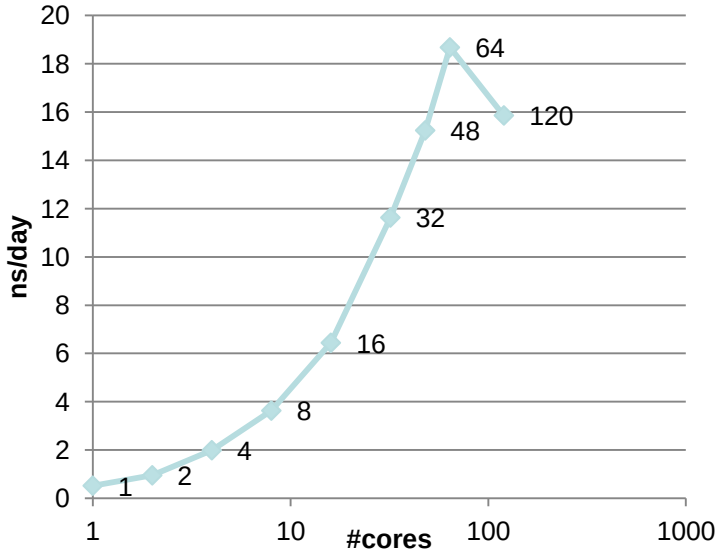
$$S(N) = \frac{1}{1-P}$$

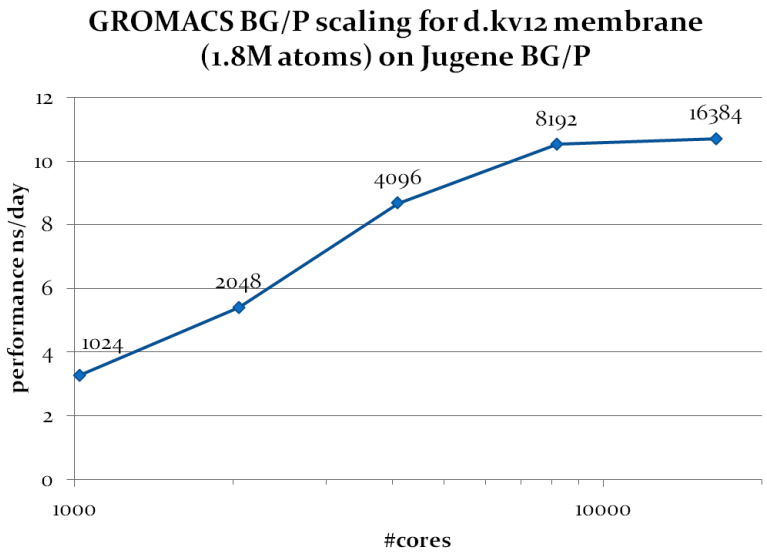
i.e. the max speedup is not dependent on N. Must minimise P if we want to many processors.

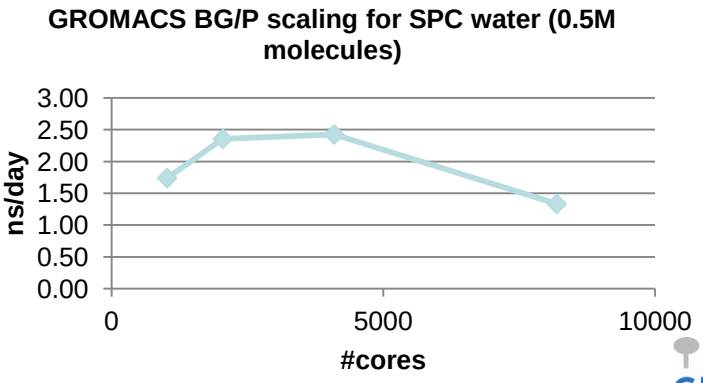
The scaling limit



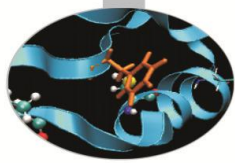
- Most application codes do not scale up-to thousands of cores.
- Sometimes the algorithm can be improved but frequently there is a hard limit dictated by the size of the input.
- For example, in codes where parallelism is based on domain decomposition (e.g. molecular dynamics) no. of atoms may be < no. of cores available.







Parallel Scaling



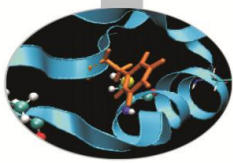
The parallel scaling is important because funding bodies insist on a minimum level of parallelism.

Computer System	Minimum Parallel Scaling	Max memory/core (Gb)
Curie	Fat Nodes 128 Thin Nodes 512 Hybrid 32	4 4 3
Fermi	2048 (but typically >=4096)	1
SuperMUC	512 (typically >=2048)	*
Hornet	2048	*
Mare Nostrum	1024	2Gb

* should use a substantial fraction of available memory

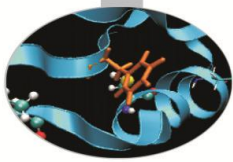
Minimum scaling requirements for PRACE Tier-0 computers for calls in 2013

Other software difficulties

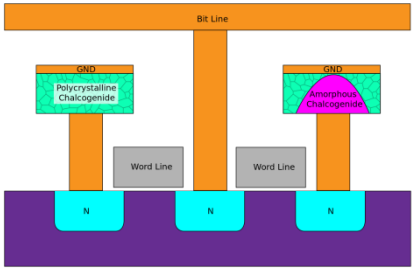


- Legacy applications (includes most scientific applications) not designed with good software engineering principles. Difficult to parallelise programs with many global variables, for example.
- Memory/core decreasing.
- I/O heavy impact on performance, esp. for BlueGene where I/O is handled by dedicated nodes.
- Checkpointing and resilience.
- Fault tolerance over potentially many thousands of threads.
  - In MPI, if one task fails all tasks are brought down.

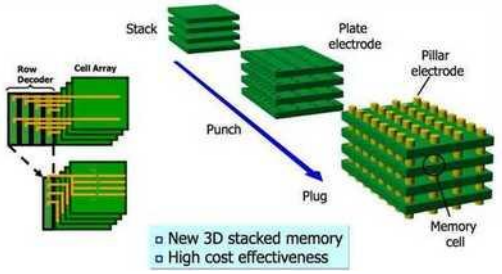
Memory and accelerator advances – things to look out for



- Memory
  - In HPC memory is generally either fast, small cache (SRAM) close to the CPU or larger, slower, main memory (DRAM).But memory technologies and ways of accessing it are evolving.
    - Non-volatile RAM (NVRAM). Retains information when power switched off. Includes flash and PCM (Phase Change Memory).
    - 3D Memory. *DRAM chips assembled in "stacks" to provide a* denser memory packing (e.g. Intel, GPU).

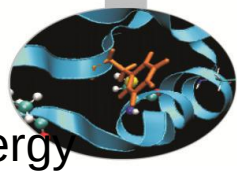


- NVIDIA GPU
  - NVLINK, high-speed link (80 Gb/s) to replace PCI-E (16 Gb/s).
  - Unified Memory between CPU and GPU to avoid separate memory allocations.
  - GPU + IBM Power8 for new hybrid supercomputer (OpenPower).



- Intel Xeon PHI (Knights Landing)
  - Upgrade to Knights Corner. More memory and cores, faster internal network and possibility to boot as standalone host.

Energy Efficiency



- Hardware sensors can be integrated into batch systems to report the energy consumption of a batch job.
- Could be used to charge users according to energy consumed instead of resources reserved.

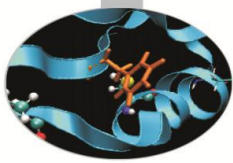
PowerDAM commands

Measures directly the energy in kWh (=3600 kJ).
Current implementation still very experimental.

```
ets --system=Eurora --job=429942.node129

EtS is: 0.173056 kWh
Computation:    99 %
Networking:     0 %
Cooling:        0 %
Infrastructure: 0 %
```

Energy Efficiency



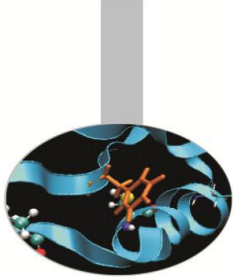
Energy consumption of GROMACS on Eurora.

PBS Job id	nodes	Clock freq (GHz)	#gpus	Walltime (s)	Energy (kWh)	Perf (ns/day)	Perf-Energy (ns/kJ)
429942	1	2	0	1113	0.17306	10.9	69.54724
430337	2	2	0	648	0.29583	18.6	62.87395
430370	1	3	0	711	0.50593	17.00	33.60182
431090	1	3	2	389	0.42944	31.10	72.42023

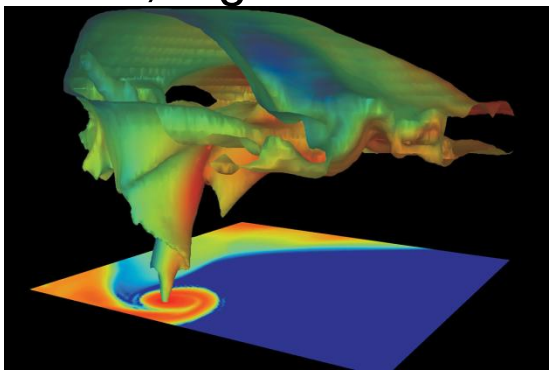
Exercises:

- compare clock freq 2 Ghz with 3 Ghz
- clock freq 3 Ghz with and without GPU

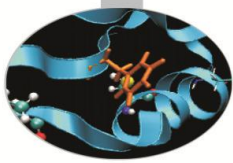
"approximate computing"



- Energy efficiency is a big deal - next-generation *exaflop"machines*, which are capable of 10^{18} operations a second, could consume as much as 100 megawatts, the output of a small power station.
- (In terms of flops, the human brain is 10,000 times more efficient.)
- Solution? Reduce the accuracy (precision) of calculations by lowering the voltage supplied to least significant bits.
- Already being used in audio-visual applications. Could become important as well in HPC, e.g. weather modelling.



Wrap-up



- HPC is only possible via parallelism and this must increase to maintain performance gains.
- Parallelism can be achieved at many levels but because of limited code scalability with traditional cores increasing role for accelerators (e.g. GPUs, MICs). The Top500 is becoming now becoming dominated by hybrid systems.
- Hardware trends forcing code re-writes with OpenMP, OpenCL, CUDA, OpenACC, etc in order to exploit large numbers of threads.
- Unfortunately, for many applications the parallelism is determined by problem size and not application code.
- Energy efficiency (Flops/Watt) is a crucial issue. Some batch schedulers already report energy consumed and in the near future your job priority may depend on predicted energy consumption.
