

### INTRODUCTION TO MPI – MPI DATATYPES

Introduction to Parallel Computing with MPI and OpenMP

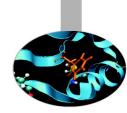

24 november 2017

a.marani@cineca.it

# **DERIVED DATATYPE**

#### You may need to send messages that contain:

1. non-contiguous data of a single type (e.g. a sub-block of a matrix)

2. contiguous data of mixed types (e.g., an integer count, followed by a sequence of real numbers)

3. non-contiguous data of mixed types

#### **Possible solutions:**

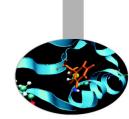

- 1. make multiple MPI calls to send and receive each data element
  - $\rightarrow$  If advantadgeous, copy data to a buffer before sending it
- 2. use MPI\_pack/MPI\_Unpack to pack data and send packed data (datatype MPI\_PACKED)
- 3. use MPI\_BYTE to get around the datatype-matching rules. Like MPI\_PACKED, MPI\_BYTE can be used to match any byte of storage (on a byte-addressable machine), irrespective of the datatype of the variable that contains this byte.

Additional latency costs due to multiple calls Additional latency costs due to memory copy

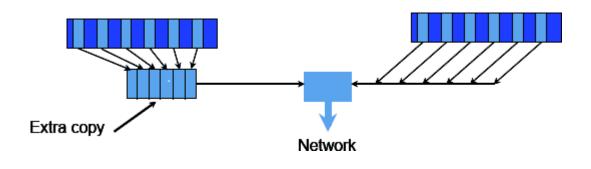

# **DERIVED DATATYPE**

#### Datatype solution:

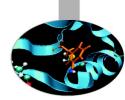

- 1. The idea of MPI derived datatypes is to provide a simple, portable, elegant and efficient way of communicating non-contiguous or mixed types in a message.
  - During the communication, the datatype tells MPI system where to take the data when sending or where to put data when receiving.
- 2. The actual performances depend on the MPI implementation
- 3. Derived datatypes are also needed for getting the most out of MPI-I/O.

### DEFINITION

A **general datatype** is an **opaque object** able to describe a buffer layout in memory by specifing:

- A sequence of basic datatypes
- A sequence of integer (byte) displacements.

Typemap = {(type 0, displ 0), ... (type n-1, displ n-1)}

- pairs of basic types and displacements (in byte)

#### Type signature = {type 0, type 1, ... type n-1}

- list of types in the typemap
- gives size of each elements
- tells MPI how to interpret the bits it sends and received

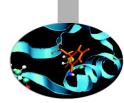

#### **Displacement**:

- tells MPI where to get (when sending) or put (when receiving)

#### **TYPEMAP**

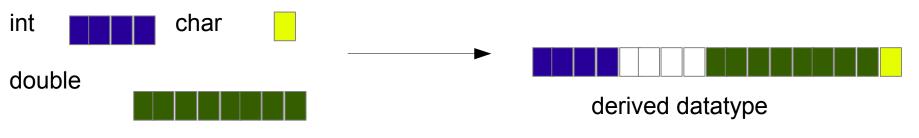

#### Example:

Basic datatype are particular cases of a general datatype, and are predefined:

**MPI\_INT** = {(int, 0)}

General datatype with typemap

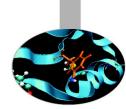

#### Typemap = {(int,0), (double,8), (char,16)}

# **HOW TO USE**

General datatypes (differently from C or Fortran) are created (and destroyed) at run-time through calls to MPI library routines.

#### Implementation steps are:

- 1. Creation of the datatype from existing ones with a datatype constructor.
- 2. Allocation (committing) of the datatype before using it.
- 3. Usage of the derived datatype for MPI communications and/or for MPI-I/O
- 4. Deallocation (**freeing**) of the datatype after that it is no longer needed.

#### MPI\_TYPE\_COMMIT (datatype) INOUT datatype: datatype that is committed (handle)

# Before it can be used in a communication or I/O call, each derived datatype has to be committed

**MPI\_TYPE\_FREE** (datatype)

٠

INOUT datatype: datatype that is freed (handle)

Mark a datatype for deallocation Datatype will be deallocated when all pending operations are finished

Before it can be used in a communication or I/O call, each derived datatype has to be committed

New datatypes have to be declared as MPI\_Datatype (in C) or INTEGER (in Fortran)

**MPI\_TYPE\_FREE** (datatype)

INOUT datatype: datatype that is freed (handle)

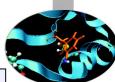

Mark a datatype for deallocation Datatype will be deallocated when all pending operations are finished

٠

## **MPI TYPE CONTIGUOUS**

#### MPI\_TYPE\_CONTIGUOUS (count, oldtype, newtype)

IN count: replication count (non-negative integer) IN oldtype: old datatype (handle) OUT newtype: new datatype (handle)

MPI\_TYPE\_CONTIGUOUS constructs a typemap consisting of the **replication** of a **datatype** into contiguous locations.

newtype is the datatype obtained by concatenating count copies of oldtype.

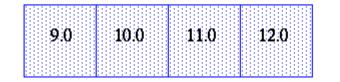

#### **MPI TYPE CONTIGUOUS**

count = 4; MPI\_Type\_contiguous(count, MPI\_FLOAT, &rowtype);

1.0	2.0	3.0	4.0
5.0	6.0	7.0	8.0
9.0	10.0	11.0	12.0
13.0	14.0	15.0	16.0

MPI\_Send(&a[2][0], 1, rowtype, dest, tag, comm);

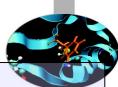

1 element of row type

a[4][4]

### **MPI TYPE VECTOR**

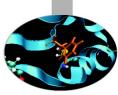

MPI\_TYPE\_VECTOR (count, blocklength, stride, oldtype, newtype) IN count: Number of blocks (non-negative integer) IN blocklen: Number of elements in each block (non-negative integer) IN stride: Number of elements (NOT bytes) between start of each block (integer) IN oldtype: Old datatype (handle) OUT newtype: New datatype (handle)

Consists of a number of elements of the same datatype repeated with a certain stride

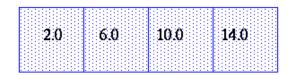

#### count = 4; blocklength = 1; stride = 4; MPI\_Type\_vector(count, blocklength, stride, MPI\_FLOAT, &columntype);

1.0	2.0	3.0	4.0	
5.0	6.0	7.0	8.0	a[4][4]
9.0	10.0	11.0	12.0	νι ' <u>ι</u> ι'ι
13.0	14.0	15.0	16.0	

MPI\_Send(&a[0][1], 1, columntype, dest, tag, comm);

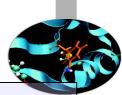

1 element of columntype

•

### MPI TYPE HVECTOR

#### MPI\_TYPE\_CREATE\_HVECTOR (count, blocklength, stride, oldtype, newtype)

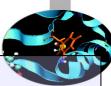

IN count: Number of blocks (non-negative integer) IN blocklen: Number of elements in each block (non-negative integer) IN stride: Number of bytes between start of each block (integer) IN oldtype: Old datatype (handle) OUT newtype: New datatype (handle)

It's identical to MPI\_TYPE\_VECTOR, except that stride is given in bytes, rather than in elements • "H" stands for heterogeneous

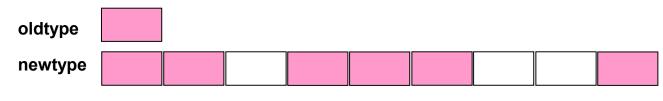

### **MPI TYPE INDEXED**

MPI\_TYPE\_INDEXED (count, array\_of\_blocklengths, array\_of\_displacements, oldtype, newtype)
IN count: number of blocks – also number of entries in array\_of\_blocklenghts and array\_of\_displacements (non-negative integer)
IN array\_of\_blocklengths: number of elements per block (array of non-negative integers)
IN array\_of\_displacements: displacement for each block, in multiples of oldtype extent (array of integer)
IN oldtype: old datatype (handle)
OUT newtype: new datatype (handle)

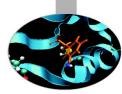

Creates a new type from blocks comprising identical elements The size and displacements of the blocks can vary

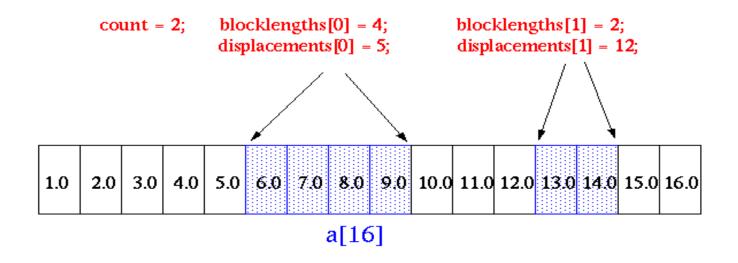

count=3, array\_of\_blocklenghths=(/2,3,1/), array\_of\_displacements=(/0,3,8/)

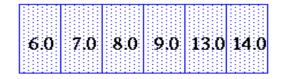

MPI\_Type\_indexed(count, blocklengths, displacements, MPI\_FLOAT, &indextype);

MPI\_Send(&a, 1, indextype, dest, tag, comm);

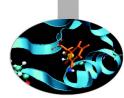

1 element of indextype

# MPI TYPE INDEXED EXAMPLE (FORTRAN)

```
! upper triangular matrix
real, dimension(100,100) :: a
integer, dimension(100) :: displ, blocklen
integer :: i, upper, ierr
```

```
! compute start and size of the columns
do i=1,100
displ(i) = 100*(i-1)+1
```

```
blocklen(i) = i
```

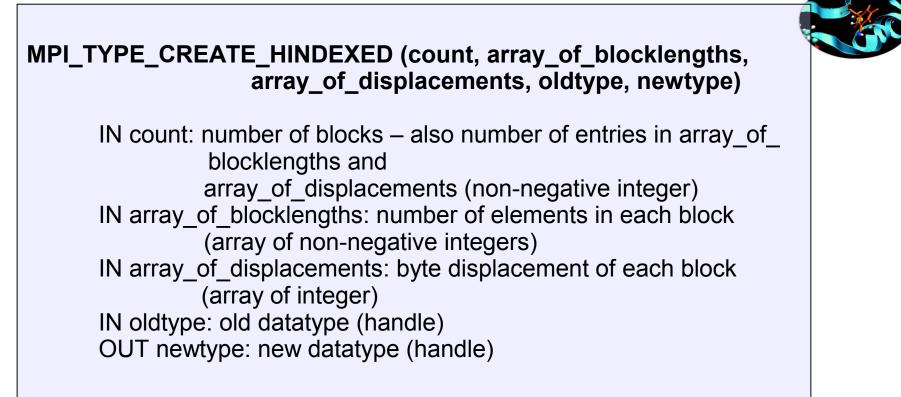

end do

! create and commit a datatype for upper triangular matrix CALL MPI\_TYPE\_INDEXED (100, blocklen, disp, MPI\_DOUBLE, upper,ierr) CALL MPI\_TYPE\_COMMIT (upper,ierr) ! ... send it ... CALL MPI\_SEND (a, 1, upper, dest, tag, MPI\_COMM\_WORLD, ierr) MPI\_Type\_free (upper, ierr)

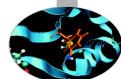

#### **MPI TYPE HINDEXED**

This function is identical to MPI\_TYPE\_INDEXED, except that block displacements in array\_of\_displacements are specified in bytes, rather that in multiples of the oldtype extent

# SuperComputing Applications and Innovation

#### MPI\_TYPE\_CREATE\_INDEXED\_BLOCK (count, blocklengths, array\_of\_displacements, oldtype, newtype)

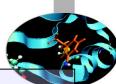

IN count: length of array of displacements (non-negative integer) IN blocklengths: size of block (non-negative integer) IN array\_of\_displacements: array of displacements (array of integer) IN oldtype: old datatype (handle) OUT newtype: new datatype (handle)

Similar to MPI\_TYPE\_INDEXED, except that the block-length is the same for all blocks.

There are many codes using indirect addressing arising from unstructured grids where the blocksize is always 1 (gather/scatter). This function allows for constant blocksize and arbitrary displacements.

#### **MPI TYPE SUBARRAY**

MPI\_TYPE\_CREATE\_SUBARRAY (ndims, array\_of\_sizes, array\_of\_subsizes, array\_of\_starts, order, oldtype, newtype)

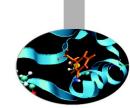

IN ndims: number of array dimensions (positive integer)
IN array\_of\_sizes: number of elements of type oldtype in each dimension of the full array (array of positive integers)
IN array\_of\_subsizes: number of elements of type oldtype in each dimension of the subarray (array of positive integers)
IN array\_of\_starts: starting coordinates of the subarray in each dimension (array of non-negative integers)
IN order: array storage order flag (state: MPI\_ORDER\_C or MPI\_ORDER\_FORTRAN)
IN oldtype: array element datatype (handle)
OUT newtype: new datatype (handle)

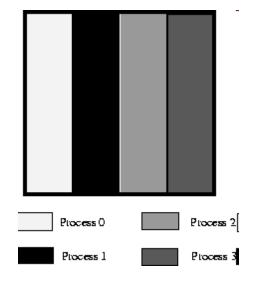

The subarray type constructor creates an MPI datatype describing an n dimensional subarray of an n-dimensional array. The subarray may be situated anywhere within the full array, and may be of any nonzero size up to the size of the larger array as long as it is confined within this array.

# MPI TYPE SUBARRAY EXAMPLE (C)

**MPI\_TYPE\_CREATE\_SUBARRAY** (ndims, array\_of\_sizes, array\_of\_subsizes, array\_of\_starts, order, oldtype, newtype)

```
double subarray[100][25];
MPI_Datatype filetype;
int sizes[2], subsizes[2], starts[2];
int rank;
```

MPI\_Comm\_rank(MPI\_COMM\_WORLD, &rank);

```
sizes[0]=100; sizes[1]=100;
subsizes[0]=100; subsizes[1]=25;
starts[0]=0; starts[1]=rank*subsizes[1];
```

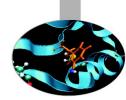

MPI\_Type\_create\_subarray(2, sizes, subsizes, starts, MPI\_ORDER\_C, MPI\_DOUBLE, &filetype);

MPI\_Type\_commit(&filetype);

#### **SIZE AND EXTENT**

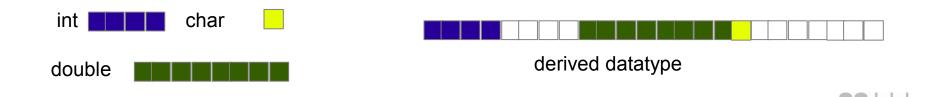

The MPI datatype for structures - MPI\_TYPE\_CREATE\_STRUCT - requires dealing with memory addresses and further concepts:

**Typemap:** pairs of basic types and displacements

**Extent:** The **extent** of a datatype is the span from the lower to the upper bound **(including "holes")** 

Size: The size of a datatype is the net number of bytes to be transferred (without "holes")

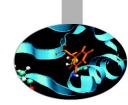

•

٠

٠

٠

### **SIZE AND EXTENT**

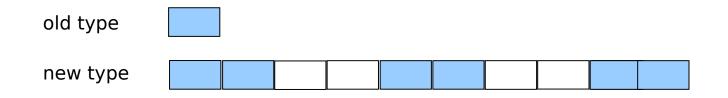

#### **Basic datatypes:**

size = extent = number of bytes used by the compiler

#### **Derived datatypes:**

extent include holes but...

beware of the type vector: final holes are a figment of our imagination

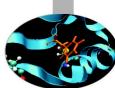

size = 6 x size of "old type"
extent = 10 x extent of "old type"

٠

### QUERY SIZE AND EXTENT OF DATATYPE

Returns the total number of bytes of the entry datatype

#### MPI\_TYPE\_SIZE (datatype, size)

IN datatype: datatype (handle)

OUT size: datatype size (integer)

Returns the lower bound and the extent of the entry datatype

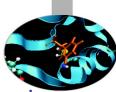

#### **MPI\_TYPE\_EXTENT** (datatype, lb, extent)

IN datatype: datatype to get information on(handle)OUT lb: lower bound of datatype (integer)OUT extent: extent of datatype (integer)

### EXTENT

Extent controls how a datatype is used with the count field in a send and similar MPI operations

Consider

٠

call MPI\_Send(buf,count,datatype,...)

```
What actually gets sent?
```

do i=0,count-1
 call MPI\_Send(bufb(1+i\*extent(datatype)),1,datatype,...)
enddo

where *bufb* is a byte type like *integer\*1* 

*extent* is used to decide where to send from (or where to receive to in MPI\_Recv) for count>1

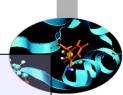

- Normally, this is right after the last byte used for (i-1)

•

### **MPI TYPE STRUCT**

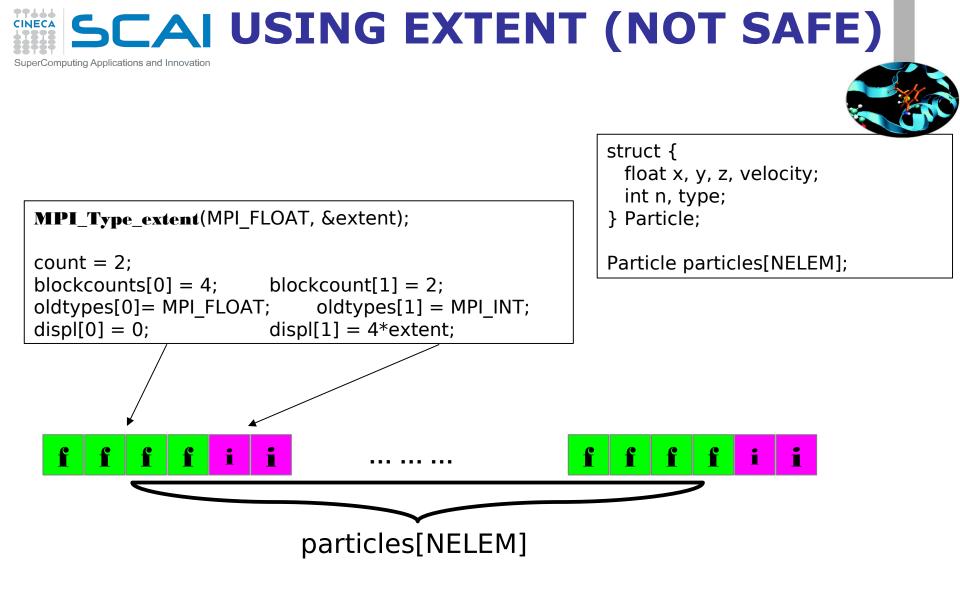

MPI\_TYPE\_CREATE\_STRUCT (count, array\_of\_blocklengths, array\_of\_displacements, array\_of\_oldtypes, newtype )

IN count: number of blocks (non-negative integer) -- also number of entries the following arrays
IN array\_of\_blocklenghts: number of elements in each block (array of non-negative integer)
IN array\_of\_displacements: byte displacement of each block (array of integer)
IN array\_of\_oldtypes: type of elements in each block (array of handles to datatype objects)
OUT newtype: new datatype (handle)

This subroutine returns a new datatype that represents count blocks. Each block is defined by an entry in array\_of\_blocklengths, array\_of\_displacements and array\_of\_types.

- Displacements are expressed in bytes (since the type can change!)
  - To gather a mix of different datatypes scattered at many locations in space into one datatype that can be used for the communication.

MPI\_Type\_struct (count, blockcounts, displ, oldtypes, &particletype);
MPI\_Type\_commit(&particletype);

# USING EXTENT (NOT SAFE)

struct {

float x, y, z, velocity; int n, type; } Particle;

Particle particles[NELEM];

int count, blockcounts[2]; MPI\_Aint displ[2]; MPI\_Datatype particletype, oldtypes[2];

count = 2; blockcounts[0] = 4; blockcount[1] = 2; oldtypes[0]= MPI\_FLOAT; oldtypes[1] = MPI\_INT;

**MPI\_Type\_extent**(MPI\_FLOAT, &extent); displ[0] = 0; displ[1] = 4\*extent;

**MPI\_Type\_create\_struct** (count, blockcounts, displ, oldtypes, &particletype);

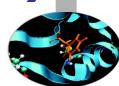

MPI\_Type\_commit(&particletype);

MPI\_Send (particles, NELEM, particletype, dest, tag,

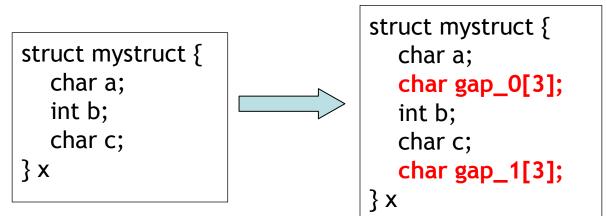

MPI\_COMM\_WORLD);

**MPI\_Free**(&particletype);

SCAI USING EXTENT (NOT SAFE)

• C struct may be automatically padded by the compiler, e.g.

Using extents to handle structs is not safe! Get the addresses

MPI_GET_ADDRESS (location, address)					
IN location: location in caller memory (choice)					
OUT address: address of location (integer)					

- The address of the variable is returned, which can then be used to determine the correct relative dispacements
- Using this function helps with portability

# **USING DISPLACEMENTS**

struct PartStruct {
 char class;
 double d[6];
 int b[7];
} particle[100];

MPI\_Datatype ParticleType; int count = 3; MPI\_Datatype type[3] = {MPI\_CHAR, MPI\_DOUBLE, MPI\_INT}; int blocklen[3] = {1, 6, 7}; MPI\_Aint disp[3];

MPI\_Get\_address(&particle[0].class, &disp[0]);
MPI\_Get\_address(&particle[0].d, &disp[1]);
MPI\_Get\_address(&particle[0].b, &disp[2]);
/\* Make displacements relative \*/
disp[2] -= disp[0]; disp[1] -= disp[0]; disp[0] = 0;

**MPI\_Type\_create\_struct** (count, blocklen, disp, type, &ParticleType);

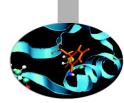

MPI\_Type\_commit (&ParticleType);

MPI\_Send(particle,100,ParticleType,dest,tag,comm); MPI\_Type\_free (&ParticleType);

### PERFORMANCE

Performance depends on the datatype - more general datatypes are often slower

some MPI implementations can handle important special cases: e.g., constant stride, contiguous structures

Overhead is potentially reduced by:

- Sending one long message instead of many small messages
- Avoiding the need to pack data in temporary buffers

Some implementations are slow
